Workstation Notifications API

Brief Overview

With the Workstation Notifications API, you can use events in any system (even if it doesn't have a WalkMe snippet) to trigger a notification in WalkMe and automatically keep your users up-to-date. Trigger Workstation notifications with a REST call to our WalkMe Notification <u>Webhook</u>.

This article will provide the information necessary to make the REST call which requires both an authentication token and a JSON payload.

Use cases

- Show alerts when a system is down or has issues (AWS or Slack servers down)
- Notify an approver when a new ServiceNow ticket requires their review
- Let users know when their Okta password expired
- Remind users who did to complete their Open Enrollment
- and more!

Any system that can call a REST API can be used to trigger notifications in Workstation.

Before you begin...

Calling the API requires some permissions and technical setup. Make sure you have access and can do the following:

- Admin Center access for your Workstation system to get the API Access Token
 - **Note**: If your organization has more than one Workstation system, you'll have to make separate API calls for each system.
- Application to configure and execute calls (i.e. Zapier or Postman) to the notification API.
 - You must have an application that can make authenticated outbound REST API calls. If you are unsure whether your organization has such an application, reach out to your IT team to discuss options.

How it works

Here's what you need from WalkMe in order to make the API trigger. Steps on how to gather everything follows.

- 1. Authentication and creating an access token
- 2. Identifying the Communication Center notification and target audience
- 3. Creating the JSON payload
- 4. Making the call

Specifically, you will find the information necessary to use a notification JSON with the following information:

- System ID
- Notification template ID
- End Users ID or Audience ID
- Notification type: popup or push
- Notification title
- Description
- Override information

Authentication and creating an access token

What is an access token?

An access token is a credential that can be used by an application to access an API. They inform the API that the bearer of the token has been authorized to access a particular action.

The access token authenticates the API call, giving the application permission to pass data from its system to Workstation.

Create access token

- 1. Go to the Admin Center
- 2. Navigate to the API Keys tab: <u>https://admin.walkme.com/account-api-keys</u>
- 3. Click Create new Key

From the Create new key panel:

- 1. Name the key
 - Tip: Indicate the *purpose of the key* in the name to help you remember later
- 2. Turn on **Notification API**
- 3. Select **Write** from the dropdown

4. Click **Create**

From the Key Details panel:

1. Copy the **Client ID** and the **Client Secret**

Save the Client Secret

You will not see the Secret again so save it somewhere accessible, you'll need it again soon.

Authentication Token

For extra support and to get the authorization token: <u>Developer page</u>

ComCenter notification and Audience ID

Create a notification template

Go to <u>Communication Center</u> and create a custom template (Learn <u>how to create a notification</u>). There's a few things to keep in mind for the notification you create for the API:

- The notification can only have **one button**
- The button action can only use the Link Action
 - You can use dynamic links or WalkMe permalinks

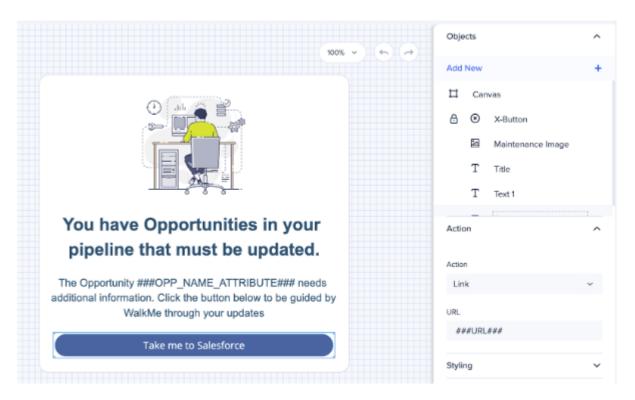

You can't edit the notification after you configured the API so make sure you are happy with your notification

Optional: Add override rules in the template

In the case that you want a notification to be personalized, either to the user or to the event that's being triggered, you can add dynamic values that the API will fill in automatically.

In the image, there are two examples of values being overridden with dynamic text that will be replaced depending on the values the API trigger.

This is an example of API notification with Salesforce which is triggered when a new lead has been assigned. It will notify the salesperson of the **opportunity name** and **link** to the lead in Salesforce.

- 1. ###OPP_NAME_ATTRIBUTE### will be replaced by Opportunity name in Salesforce
- 2. ###URL### will be replaced by an actual URL, allowing for a custom action for every user, every time the API is triggered

Note: The value name (example: OPP_NAME_ATTRIBUTE) must be **exactly** copied into the JSON so it can be replaced.

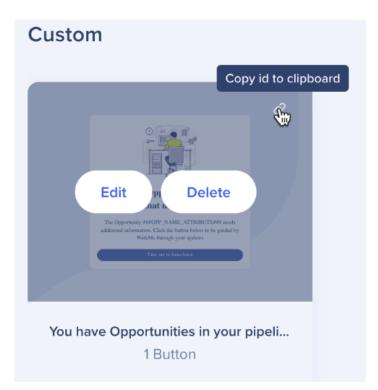

Copy required values

The following steps will connect the notification with the API.

Copy the **Custom Template ID** that you created

- 1. Go to CommCenter
- 2. Click New Notification
- 3. Under **Custom Templates** > Hover over the **corner** of the notification
- 4. Click the **copy icon** to copy the ID to your clipboard
 - Example: 75cfcba6-c320-42cb-938e-4c2bd08a43a3

walkme

Copy Target Audience ID

End User ID vs Audience

Using an audience is more efficient, but you can also target up to 100 users based on their End User ID. We recommend to make an audience if you plan to use more than 10 end user IDs

- 1. Go to Audiences
- 2. Hover over the audience > click the **3-dot menu** on the right > click **Copy ID**
 - $\circ\,$ You can add multiple audiences to the JSON
 - Example ID: cf0bd4c1-86fd-4c79-a46a-c730d6789e63

| Audiences | • |
|------------------|-----------|
| Customer Success | 0 : |
| | Duplicate |
| | C Copy ID |
| | E Archive |

Add information to the API connection application

For extra support <u>Developer page</u>.

Now it's time to fill in some information on your API connection application. For clarity, we use Zapier to explain, but we are not endorsing this application over any other. Any similar app will work.

The information used below is universally necessary on all applications:

- 1. URL = <u>https://api.walkme.com/accounts/connect/token</u>
- 2. Payload Type = (Content-Type) application/x-www-form-urlencoded
- 3. Data = grant_type \rightarrow client_credentials

| ← Untitled Zap Untitled Zap | zapier | Fix to Publish |
|--------------------------------|--|-----------------|
| | 1. Retrieve Poll in Webhooks by Zapier | <u>∧</u> Status |

| | This is performed when the Zap runs. | |
| | To continue, choose an event | |
| | ÷ | |
| ver. e7536425 | | > |

Add Basic Authentication

When using basic Auth, the clientID is the username and the client secret is used as the password.

- 1. Client ID | Client Secret (copied from Admin Center)
 - Example

0o234234234UqD5d7 | JVnD346346346436345asfgasgbPt_4T7h2_

Once you've added this information, you will be given an access token.

1. Copy your Access Token

| - 2. PO | ST in Webhooks by Zapier | | |

| hooso ann 8 | e overt | û | Rename step |
| hoose app 8 | event | ΰ | Really delete ste |
| et up action | | | Ê |
| est action | | | |
| A request | We'll use this as a sample for setting up th t was sent to Webhooks by Zapier about 1 secor | - | ır Zap. |
| | | | |
| ,O Search it | em data | | |
| O Search it token_type: expires_in: 8 access_toke | Bearer 5530 | DO1/0001/07 | oran SN2ILZ |
| token_type: expires_in: 8 | Bearer 5530 | 200000000 | ora snailz _jNH |
| token_type: expires_in: 8 | Bearer 5530 | | _jNH |
| token_type: expires_in: 8 | Bearer 5530 | | LjNH - X |
| token_type: expires_in: 8 | Bearer 5530 | DOLIGOOLIGT | _jNH - X \S |
| token_type: expires_in: 8 | Bearer 5530 | | LjNH - X IS 1 |
| token_type: expires_in: 8 | Bearer 5530 | | _jNH - X \S |
| token_type: expires_in: 8 | Bearer 5530 | | _jNH - X \s 1 ic |
| token_type: expires_in: 8 | Bearer 5530 | | LjNH - X ss 1 ic in |
| token_type: expires_in: 8 | Bearer 5530 | | _jNH _ X s 1 ic in / |
| token_type: expires_in: 8 | Bearer 5530 | | _jNH X _s 1 _vc _vn _/ _lc |

If you're using Zapier, you can delete this step after you've copied the token.

Update the JSON code

Now it's time to fill in the blanks and use the JSON code that will call the notification.

| { |
|---|
| "notification": { |
| "systemId": " <the id="" system="" workstation="">", //Required if you have more than one workstation</the> |
| system |
| "templateId": " <mark><template id=""></template></mark> ", //Required |
| "endUsersIds": [" <mark><end 1="" id="" user=""></end></mark> "," <mark><end 2="" id="" user=""></end></mark> "," <mark><></mark> "], //You need either end-user ID or |
| audience ID (you can use both), remove the one you aren't using |
| "audiencesIds": [" <mark><audience 1="" id=""></audience></mark> "," <mark><audience 2="" id=""></audience></mark> "," <mark><></mark> "], //You need either end-user ID or |
| audience ID (you can use both), remove the one you aren't using |
| "notificationType": " <how display,="" notification="" popup="" push="" v="" will="">", //Optional, default push,</how> |
| remove if not using |
| "title": " <notification appears="" as="" comcenter="" in="" notification="" table="" the="" title="">", //Optional, remove if</notification> |
| not using |
| "runtimeTitle": " <what and="" appear="" end-users="" in="" list="" push<="" td="" the="" to="" will="" workstation=""></what> |
| notification>", //Optional, remove if not using |
| "runtimeDescription": " <what and="" appear="" end-users="" i="" in="" list="" push<="" td="" the="" to="" will="" workstation=""></what> |
| message>", //Optional, remove if not using |
| "startAt": " <start date="" hh:mm="" yyyy-mm-dd="">", // Optional, default right now, timezone is UTC, you</start> |
| can add a date and no time, default time is 00:00 UTC, remove whatever you are not using |
| "endAt": " <end date="" hh:mm="" yyyy-mm-dd="">", // Optional, default 30 days from now, you can add a</end> |
| date and no time, default time is 00:00, remove whatever you are not using |
| "override": [|
| { |
| "key" : " <mark><the in="" notification="" placeholder="" replace="" string="" template="" the="" to=""></the></mark> ", |
| "value" : " <the instead="" into="" notification="" of="" placeholder="" put="" the="" to="" value="">"</the> |
| } |
| // More comma separated {key:value} pairs can follow |
| // For example, the value could be a URL that is passed from ServiceNow to open a ticket |
| |
| } |
| } |

Remove the lines you are not using

If there are optional lines that you are not filling in, remove them from your final code to prevent errors

End user and Audience ID

endUsersIds and audiencesIds are arrays and need to be written with brackets [], and each string should be separated by a comma ["<id1>","<id2>","<...>"]

Default timezone is UTC

The default timezone is UTC, but if you want to send the notification according to a different timezone, you can add or subtract from UTC. For example, "2023-05-10T11:30:00+03:00" would send at UTC+3 and the corresponding time in UTC would be "08:30:00" (subtracting 3 hours from the given time).

Here is an example of the JSON code with real data with few lines removed to make it simpler.

```
{
    "notification": {
        "systemId": "bcf4c7f5682b4aa6875a0fc9bdfa21ca",
        "templateId": "1e5afe51-2d2a-4b22-a60a-cf2d6c01d726",
        "endUsersIds": ["name@email.com"],
        "runtimeTitle": "API Test 3",
        "notificationType": "Push",
        "override": [
        {"key": "URL",
        "value": "www.someurl.com"}
    }
}
```

Make the call

Now that we have the information we need, let's connect the dots. To make the call (connect the systems to create and publish new notifications in your organization's Workstation), you'll need your **JSON** plus:

- Method: POST
- URL: <u>https://api.walkme.com/public/v1/notifications/send</u>

| Untitled Zap //Zapier | Update t | o publish |
|---|-------------|-----------|
| Set up action | Ø | |
| Method (required) | | := |
| POST | 0 | П |
| The HTTP method we'll use to perform the request. | | 4 |
| JRL (required) | | 0 |
| https://api.walkme.com/public/v1/notifications/send | | 6 |
| Any URL with a querystring will be re-encoded properly. | | 2 |
| Data Pass-Through? ® O | | |
| False | 0 | |
| f yes, request data below will be overridden with the raw data from the previous step (you are still responsible for Data | <u>more</u> | |
